Recall the one-group diffusion equation:

$$\frac{1}{v_1} \frac{\partial \phi_1(\vec{r}, t)}{\partial t} = S_1(\vec{r}, t) - \Sigma_{a,1}(\vec{r})\phi_1(\vec{r}, t) + \nabla \cdot [D_1(\vec{r})\nabla \phi_1(\vec{r}, t)]$$

Now, *assume that space and energy dependence of the flux can be separated:*

Focusing on the *spatial dependence* of the flux, we'll assume a homogeneous, steady-state, one-group system.

$$\frac{1}{v} \frac{\partial \phi(\vec{r}, t)}{\partial t} = S(\vec{r}, t) - \Sigma_s(\vec{r})\phi(\vec{r}, t) + \nabla \cdot [D(\vec{r})\nabla \phi(\vec{r}, t)]$$

Steady-state: $\frac{1}{v} \frac{\partial \phi(\vec{r}, t)}{\partial t} = 0$

Homogeneous: no material dependence on position; $\Sigma_a(\vec{r}) \rightarrow \Sigma_a$, $D(\vec{r}) \rightarrow D$

This gives us

Now, consider a plane source of strength S_0 in an infinitely absorbing medium.

The boundary conditions we'd like to enforce are that the source is zero other than at the plane, so within $\epsilon \rightarrow 0$:

We can use this to examine two sets of equations and boundary conditions.

(1) For $x < 0$, $\frac{d^2 \phi}{dx^2} - \frac{1}{L^2} \phi(x) = 0$.

Boundary conditions:

(2) For $x > 0$, $\frac{d^2\phi}{dx^2} - \frac{1}{L^2}\phi(x) = 0$.

Boundary conditions:

With the above equations and boundary conditions, we have a general solution form of (which you'll recall from your differential equations class):

From the finite flux condition, $c_2 = 0$. Then, $\phi(x) = c_1 e^{-x/L}$.

The neutron flux falls off exponentially as one moves away from the source plane with a characteristic decay length of L . This holds fairly well as long as we're not too near the source and the medium is not too strongly absorbing.

Now, consider an infinite plane centered in a slab of finite thickness a , surrounded by a vacuum.

(1) For $x > 0$, $\frac{d^2\phi}{dx^2} - \frac{1}{L^2}\phi(x) = 0$.

Boundary conditions:

(2) For $x < 0$, $\frac{d^2\phi}{dx^2} - \frac{1}{L^2}\phi(x) = 0$.

Boundary conditions:

Now, we can again write the equations as

$$\phi(x) = c_1 e^{-x/L} + c_2 e^{x/L}$$

Or, with equal validity (which we could have also done before)

You can use the boundary conditions to reach the full solution.

Now, consider a uniformly distributed source of strength $S_0 \frac{n}{cm^3 s}$ within a finite slab of width a with vacuum boundaries.

$$\frac{d^2\phi(x)}{dx^2} - \frac{1}{L^2}\phi(x) = -\frac{S_0}{D}$$

Boundary conditions: $\phi(\pm \frac{a}{2}) = 0$

Alternative boundary condition: $\left. \frac{d\phi(x)}{dx} \right|_{x=0} = 0$ (symmetry)

Now, consider a uniform source in a reflected slab, where region 2 contains the source and 1 and 3 are reflectors (high scattering compared to absorption). The center of region 2 is located at $x = 0$ and the edges of region two are at $x = \pm \frac{a}{2}$.

We start by using an equation containing the source in region 2, designating the solution ϕ_2 :

We need a collection of boundary conditions (where subscript indicates region number) that relate region 2 to the other regions:

We also need equations for regions 1 and 3, which do not have sources:

These regions have boundary conditions as well: $\lim_{x \rightarrow -\infty} |\phi_1(x)| < \infty$, $\lim_{x \rightarrow \infty} |\phi_3(x)| < \infty$

What if we want to solve a **generic diffusion problem**?

$$D\nabla^2\phi(\vec{r}) - \Sigma_a\phi(\vec{r}) = -S(\vec{r})$$

Working in 1D:

$$M\phi(x) = f(x)$$

where M is non-homogenous differential operator of order n on a differential equation:

$$a_0(x)\phi^{(n)}(x) + a_1(x)\phi^{(n-1)}(x) + \dots + a_n(x)\phi(x) = f(x)$$

for example

$$M = \frac{d^2}{dx^2} - \frac{1}{L}$$

One solution method is *variation of constants / parameters*, where we break the solution into homogeneous and particular portions:

$$M\phi_{homog}(x) = 0$$

$$M\phi_{part} = rhs$$

$$\phi(x) = \phi_{homog}(x) + \phi_{part}(x)$$

We solve the homogeneous part to yield

$$\phi_{i,h}(x), \quad i = 1, \dots, n \quad \text{independent solutions}$$

and we also know

$$\phi_{part}(x) = \sum_{i=1}^n c_i \phi_{i,h}(x)$$

where $c_i = c_i(x)$ and are differentiable functions that satisfy the conditions

$$\sum_{i=1}^n c'_i(x) \phi_{i,h}^{(j)}(x) = 0, \quad j = 0, \dots, n-1.$$

If

$$\sum_{i=1}^n c'_i \phi_{i,h}(x) = 0$$

$$\sum_{i=1}^n c'_i \phi_{i,h}^{(1)}(x) = 0$$

\vdots

$$\sum_{i=1}^n c'_i \phi_{i,h}^{(n-2)}(x) = 0$$

then

$$\sum_{i=1}^n c'_i \phi_{i,h}^{(n-1)}(x) = \frac{f(x)}{a_0(x)}$$

which indicates

$$c_i(x) = \int dx \, c'_i(x) .$$

For $n = 2$:

$$\phi_1(x)c'_1(x) + \phi_2(x)c'_2(x) = 0$$

$$\phi_1^{(1)}(x)c'_1(x) + \phi_2^{(1)}(x)c'_2(x) = \frac{f(x)}{a_0(x)}$$

$$\phi_{part} = c_1(x)\phi_1(x) + c_2(x)\phi_2(x)$$

$$a_0(x)\phi^{(2)}(x) + a_1(x)\phi^{(1)}(x) + a_2(x)\phi(x) = 0$$

$$\phi^{(1)}(x) = c'_1(x)\phi_1(x) + c_1(x)\phi'_1(x) + c'_2(x)\phi_2(x) + c_2(x)\phi'_2(x)$$

$$c_i(x) = \int dx c'_i(x) = A_i + \psi_i(x)$$

$$\phi(x) = \sum_{i=1}^n A_i \phi_i(x) + \sum_{i=1}^n \psi_i(x) \phi_i(x)$$

For $n = 2$: $\phi(x) = A_1 \phi_1(x) + A_2 \phi_2(x) + \psi_1(x) \phi_1(x) + \psi_2(x) \phi_2(x)$
